Abstract (Basic): EP 503916 A

A method (I) of selecting monoclonal anti-idiotype antibody reagents useful in vaccine formulations comprises: (a) preparing human polyclonal anti-gp120 antibodies (Abls); (b) generating a 1st plurality of monoclonal anti-idiotype antibodies (Ab2s) that immunologically binds with said antibodies; (c) selecting a 2nd plurality of antibodies form the first plurality that immunogically binds with said antibodies ; (c) selecting a 2nd plurality of antibodies from the first plurality that immunogically bind antiantibodies that neutralise in vitro multiple strains of DIV; gp120 and (d) selecting a 3rd plurality from the 2nd that generate anti-idiotype antibody (Ab3) response in a primate host, immunologically bind with gp120 and neutralise multiple strains of

HIV in vitro. Also new are: (1) a monoclonal anti-idiotype antibody reagent selected in (I); (2) a monoclonal anti-idiotype capable of eliciting a group neutralising anti-HIV antibody response in humans; (3) a hybridoma cell line capable of producing the antibody of (2); (4) a hybridoma cell line with ATCC, Rockville MF No.HB 10701 and the antibody produced by it; (5) a monoclonal antibody which elicits a substantially equivalent immune response in humans, or reacts and antibody as the antibodies of competes with the same anti-gp120 (2) and (4); and (6) a vaccine formulation comprising the above antibodies in admixture with a pharmaceutically acceptable carrier.

USE - Useful for the treatment and prevention of HIV infection.
